

Cell-cycle duration / growth phase sets the H3K27me3 brake on CyclinD1 (replicative-dilution frequency = 1/period)

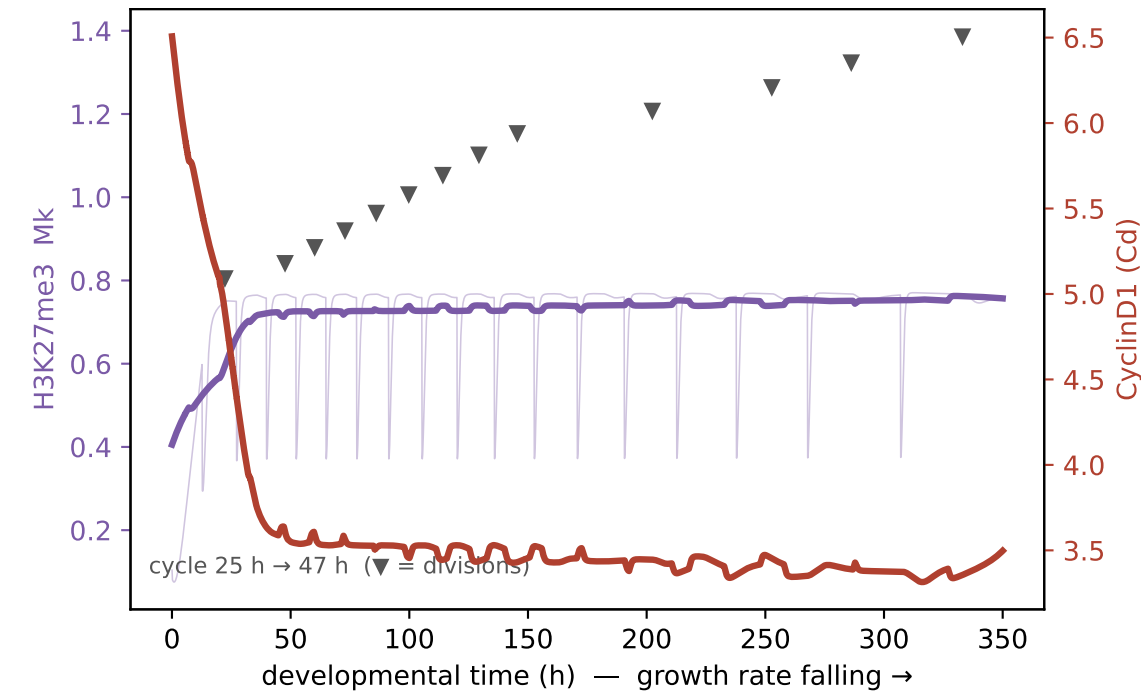

(A) Longer cycle → mark rebuilds more between S-phase halvings

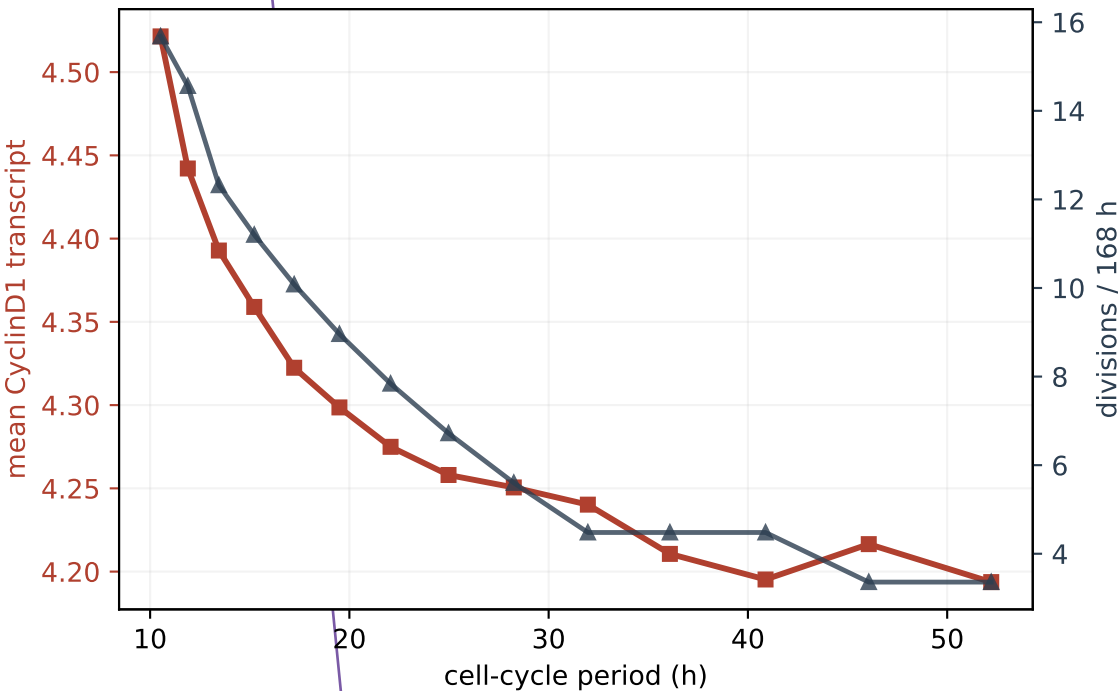

(B) Impact of replicative dilution diminishes as duration increases

(C) As the cell cycle slows, the mark accumulates and CyclinD1 is progressively repressed

(D) The consequence: slower cycle → more mark → less CyclinD1

"dilution relief"
shrinks as the
cycle lengthens
