

EZH2 tracks mitogen & buffers CyclinD1 (relief on withdrawal) — protecting GNP transit-amplifying divisions

(A) EZH2 tracks mitogen → buffers CyclinD1

EZH2 rises with mitogen; CyclinD1 flattened vs the raw drive (gain 0.85→0.47)

(B) GRADUAL decline: EZH2 tracks mitogen down → relief
buffered CyclinD1 stays above the raw drive (no undershoot)

(C) A GRADUAL temporary decline that returns
buffered CyclinD1 stays higher & recovers (rides through the dip)

(D) Commitment memory (Rb-E2F R-point)
sustained loss → exit; short dip → committed cell still divides
