

Serial H3K27 methylation (me1→me2→me3) vs a lumped mark — how the slow last step changes me3 kinetics

me0→me1→me2→me3 with FAST me1/me2 and a SLOW, rate-limiting me2→me3. Every division halves the modified fractions (new histones = me0). Serial me1/me2/me3 chain (now the default).

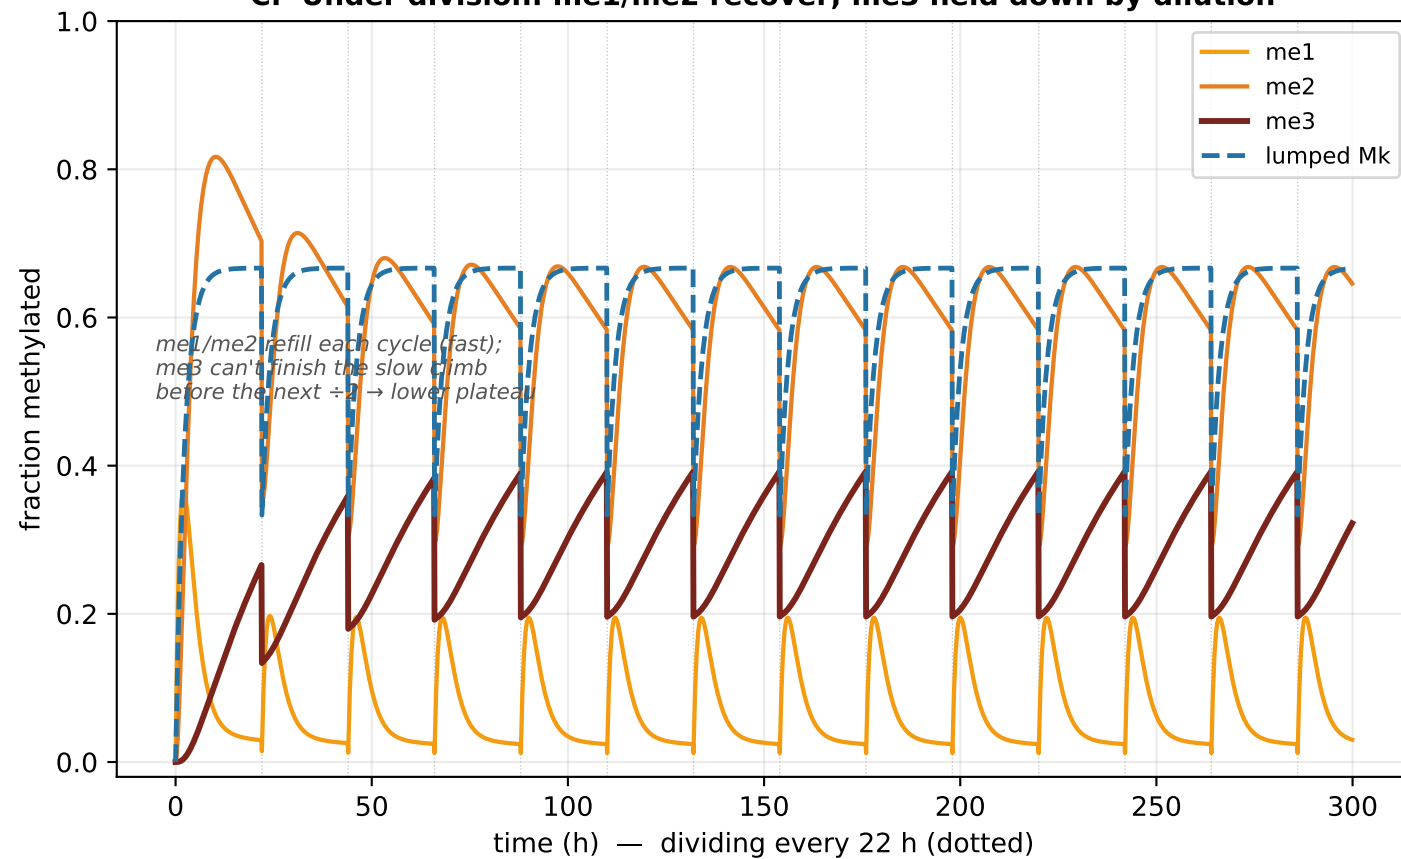

A. The serial scheme

B. Accumulation LAG: me3 builds slowly, sigmoidally

C. Under division: me1/me2 recover; me3 held down by dilution

D. me3 depends strongly on cycle speed — the lumped mark does not
