

H3K27me3 → CyclinD1 timing & cell-cycle impact (full v44 model)

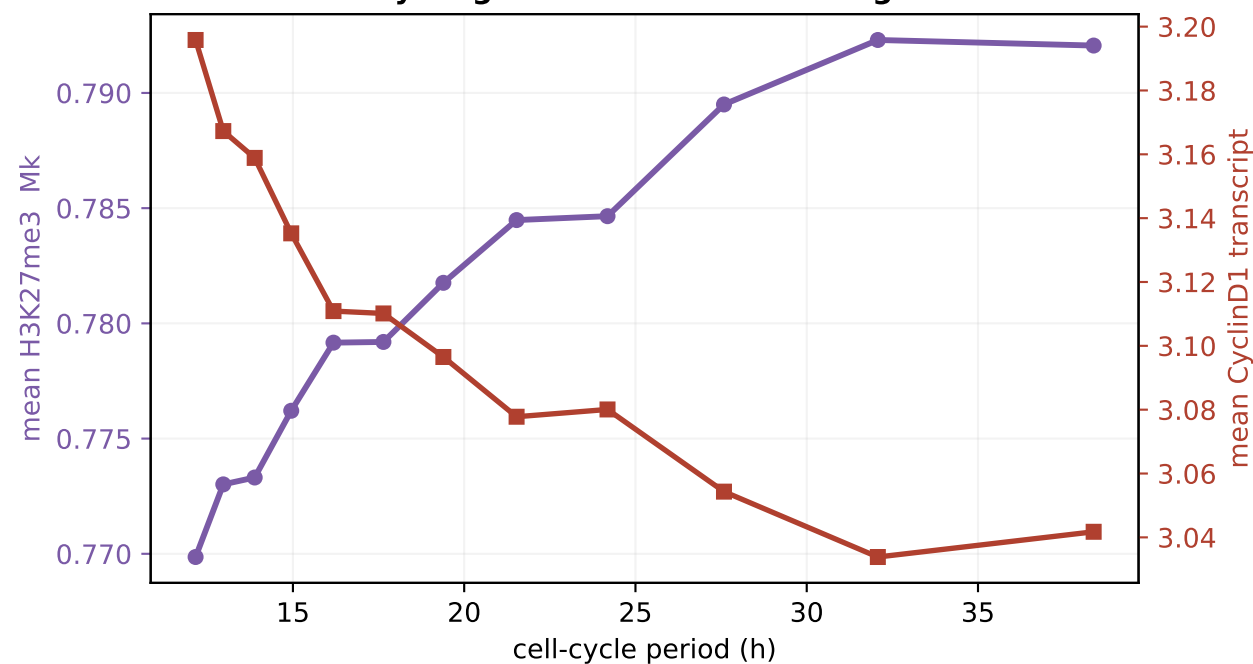

(A) De-repression timing: how fast the mark clears when the writer is inhibited

(B) Replicative dilution: the mark is halved every S phase, then rebuilds — a sawtooth clocked by the cell cycle

(C) Cell-cycle speed sets the mark: slower cycling → less dilution → stronger brake

(D) Entry timing: the brake delays cell-cycle onset to higher Hh / later time
