

CyclinD1 / commitment response to Hh FLUCTUATIONS — WITH vs WITHOUT H3K27me3 (Hh0=0.45±0.3 sine, N=1000/cond)

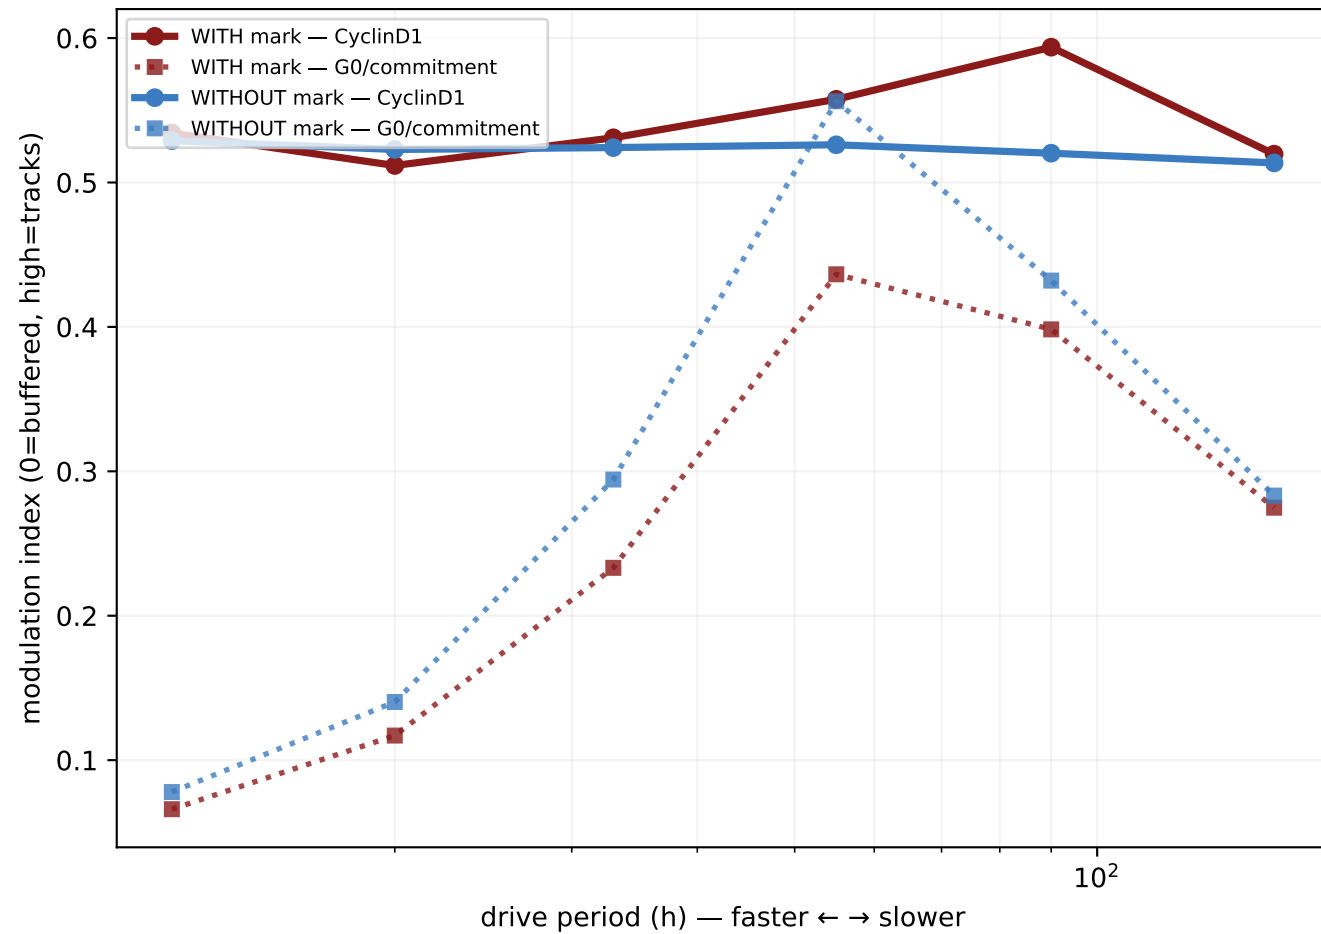

(A) FAST (T=12 h): CyclinD1 tracks Hh; WITH mark lower mean, same relative swing

(B) SLOW (T=150 h): CyclinD1 tracks the drive (both)

(C) CyclinD1 relative swing ≈ equal & flat (mark SCALES, no low-pass); G0/commitment low-pass-filtered but ~EQUAL → buffering is the cell cycle, NOT the mark

(D) The mark is a slow integrator: its own oscillation is tiny for FAST drives (can't follow), grows for SLOW — too small to buffer CyclinD1
