

TRANSIENT G0 response to Hh FLUCTUATIONS — WITH vs WITHOUT H3K27me3 repression (Hh0=0.45±0.3 sine, calibrated+mu+partition, N=1000/cond)

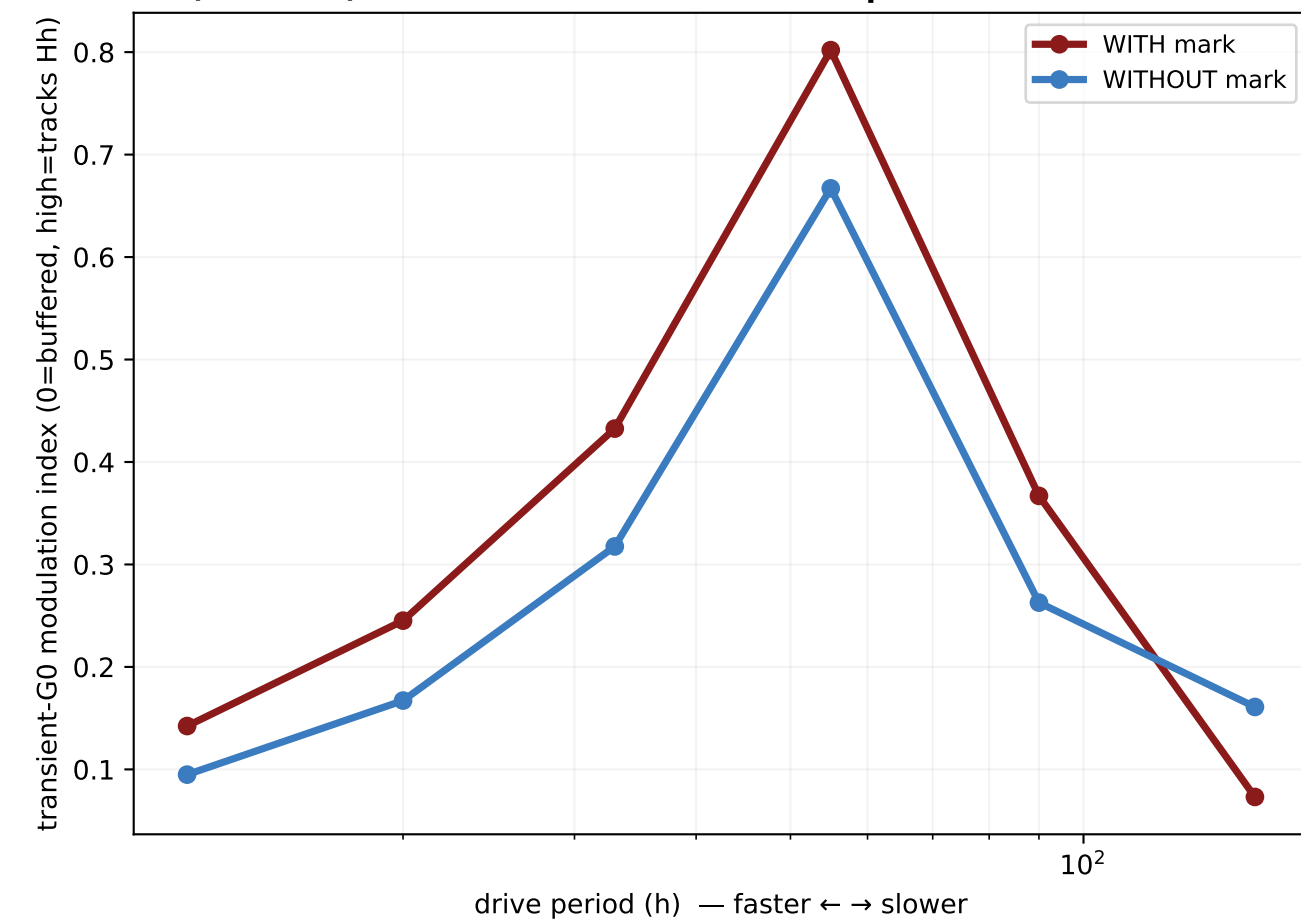

(A) FAST fluctuation (T=12 h): transient-G0 over one drive cycle
(grey=Hh; peaks at LOW Hh)

(B) SLOW fluctuation (T=150 h): transient-G0 swings fully with the drive

(C) Does transient-G0 track the fluctuation? Low at FAST drives (buffered) → rises for slower drives. Compare WITH vs WITHOUT

(D) MEAN transient-G0 (solid) & arrest (dashed) under fluctuations WITH vs WITHOUT — does the mark change how much time cells spend in G0?
