

EZH2 -| CyclinD1 feedback installs a mitogen-gated proliferation/quiescence switch (enables cell-cycle exit)

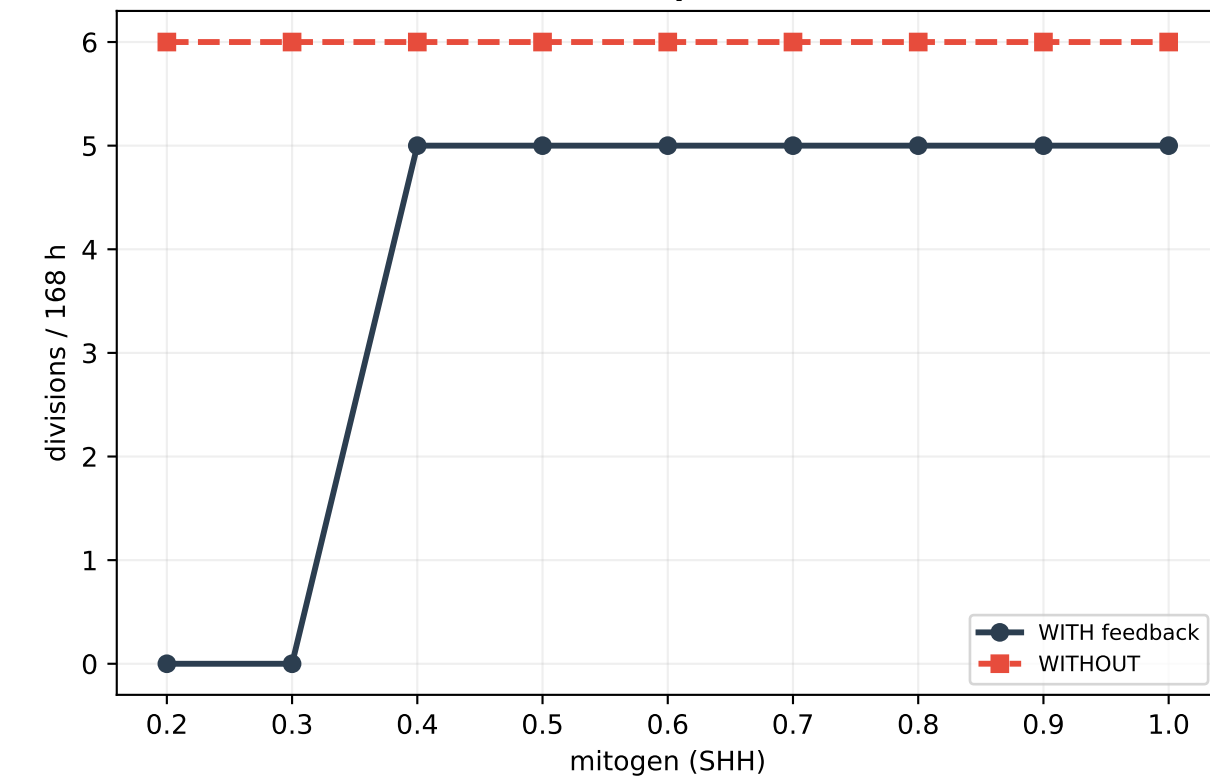

(a) The feedback holds CyclinD1 ~3x lower (under negative feedback vs unopposed mitogen drive)

(b) Without feedback CyclinD1 stays above the cycling threshold at all mitogen levels

(c) WITHOUT feedback the cell cycles even at low mitogen; the feedback installs a quiescence THRESHOLD

(d) Feedback enables QUIESCENCE below a mitogen threshold (= cell-cycle EXIT capability)
