

Response to Hh FLUCTUATIONS — WITH vs WITHOUT H3K27me3 repression (Hh0=0.45±0.3 sine, calibrated+mu+partition, N=200/cond)

(A) FAST fluctuation (T=12 h): CyclinD1 tracks Hh in BOTH
WITH mark = lower mean (repressed) but same relative swing — not buffered

(B) SLOW fluctuation (T=150 h): CyclinD1 tracks the drive (both)

(C) CyclinD1 relative swing ≈ equal & flat (mark SCALES, no low-pass);
G0/commitment (dotted) IS low-pass filtered (buffered vs fast) but ~EQUAL WITH/WITHOUT →
the buffering is the cell cycle + commitment switch, NOT the mark

(D) The mark is the slow filter: its own oscillation is small for
FAST drives (can't follow) and grows for SLOW drives
