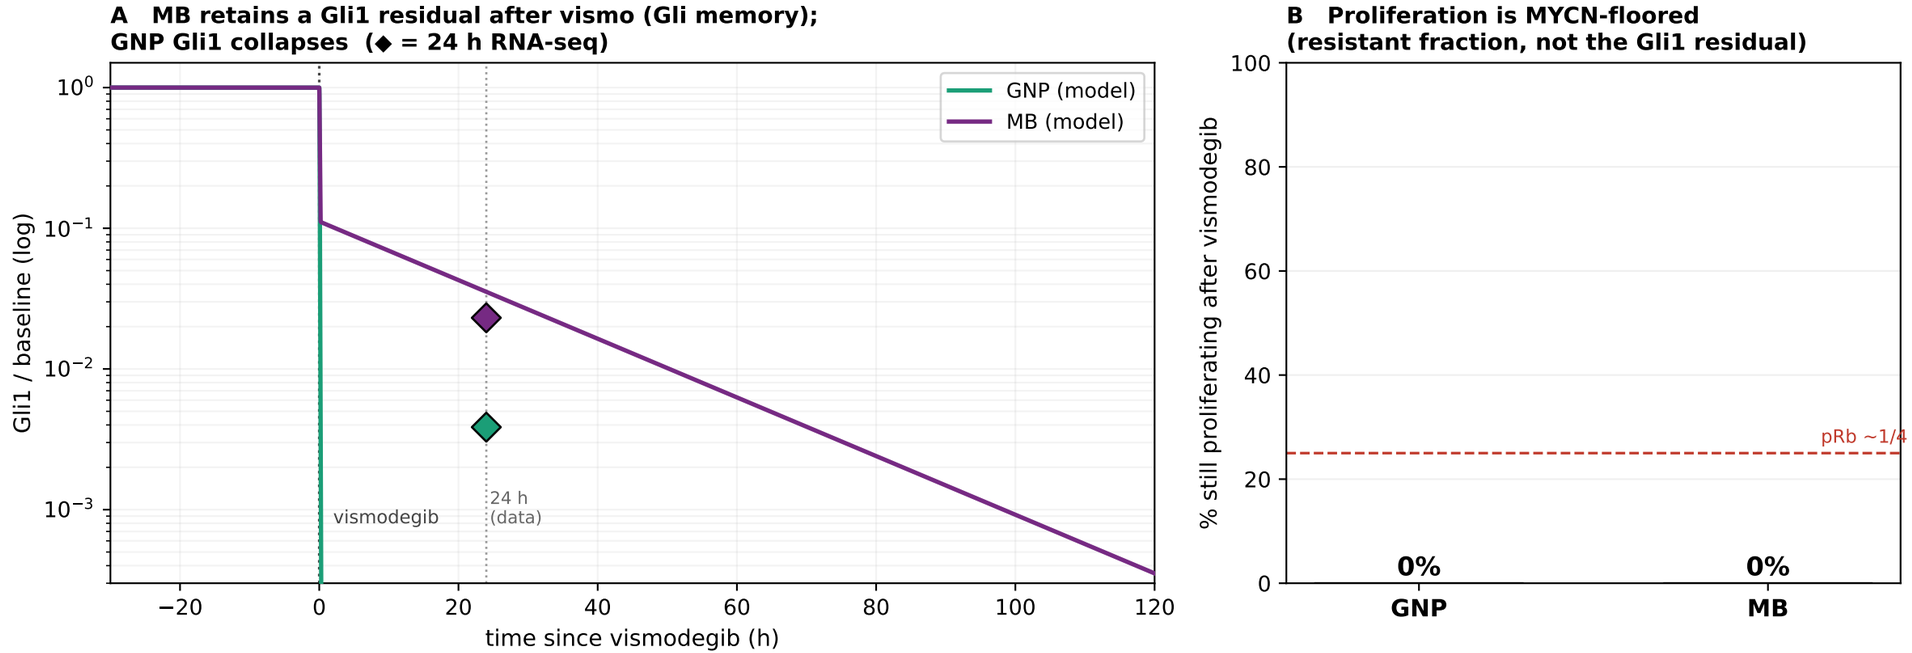
MB's reduced vismodegib sensitivity: a Gli-intrinsic Gli1 residual + a resistant fraction (v44)



MYCN floors CyclinD1 but cannot touch Gli1, so the 41x-larger MB Gli1 residual is Gli-intrinsic (the autoregulatory memory) and matches the 24 h data. Because that residual is small, CyclinD1 stays MYCN-floored -> proliferation is a resistant fraction (~pRb 1/4), set by threshold/heterogeneity.
