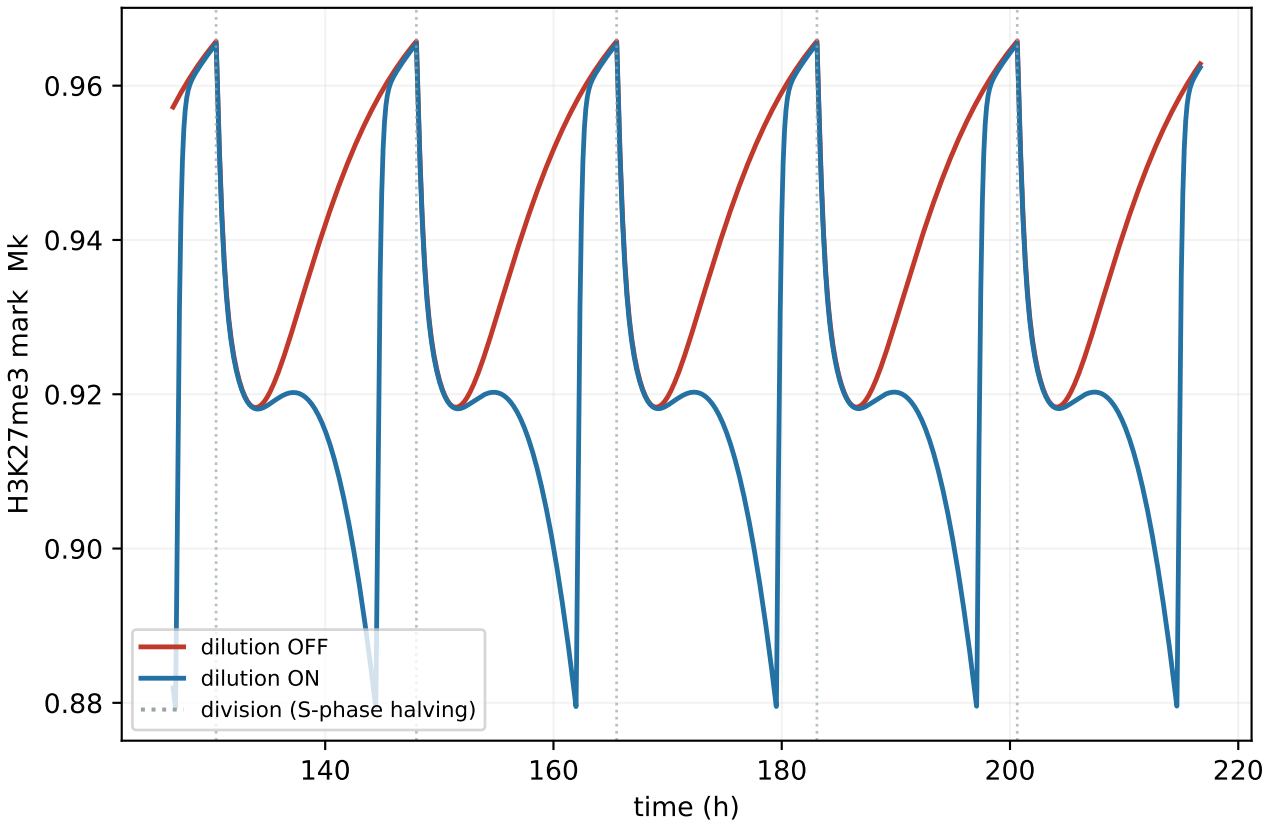
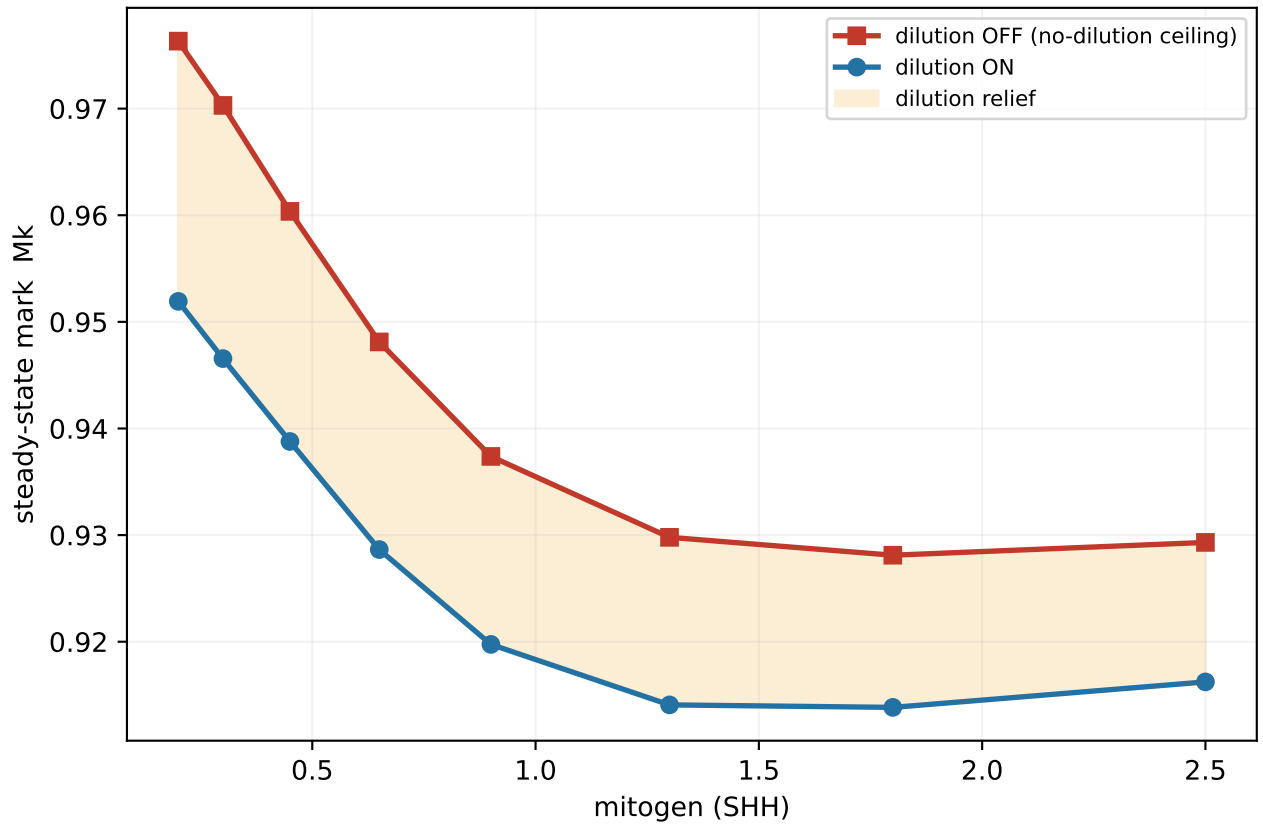
Replicative dilution of H3K27me3 limits EZH2 repression of CyclinD1 — proliferation-rate-dependent (AUM model)

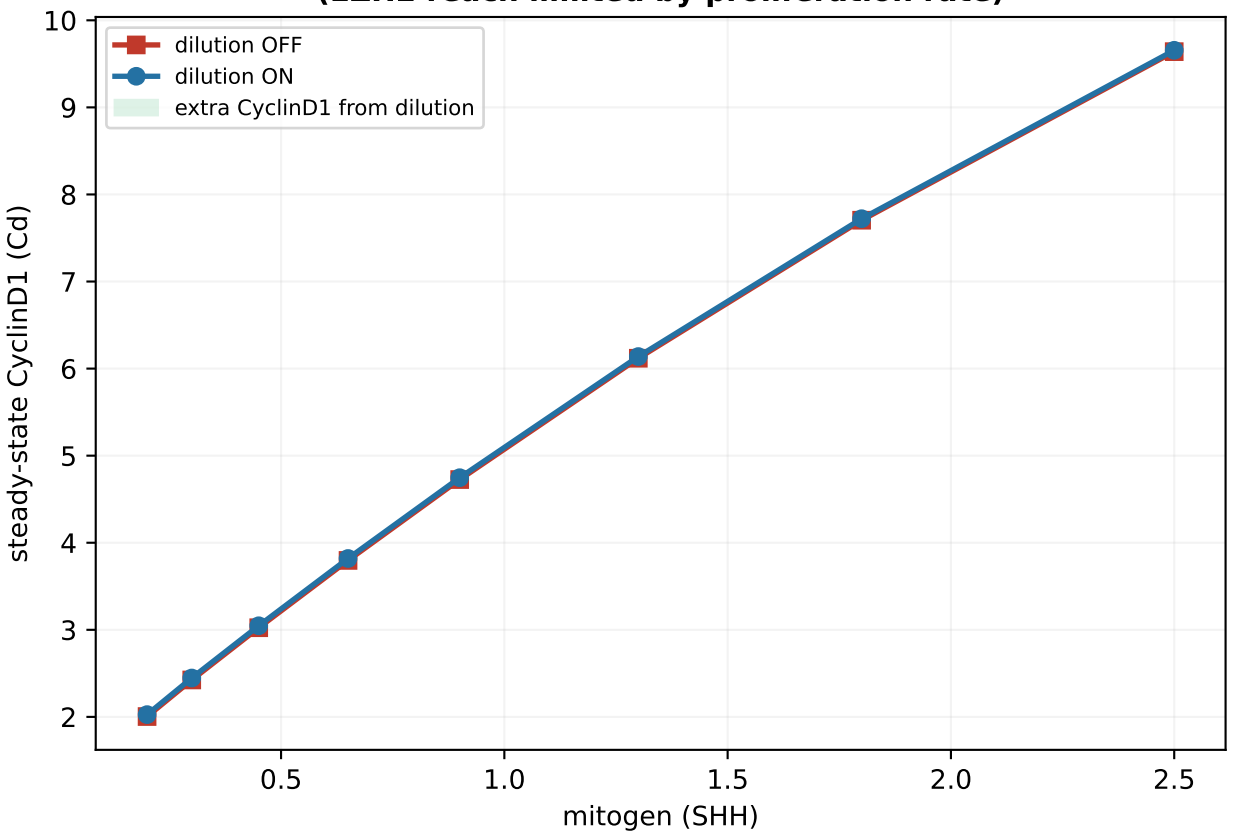
(A) The dilution mechanism (GNP, SHH=0.8)
Mk is halved each division then re-methylates (sawtooth)

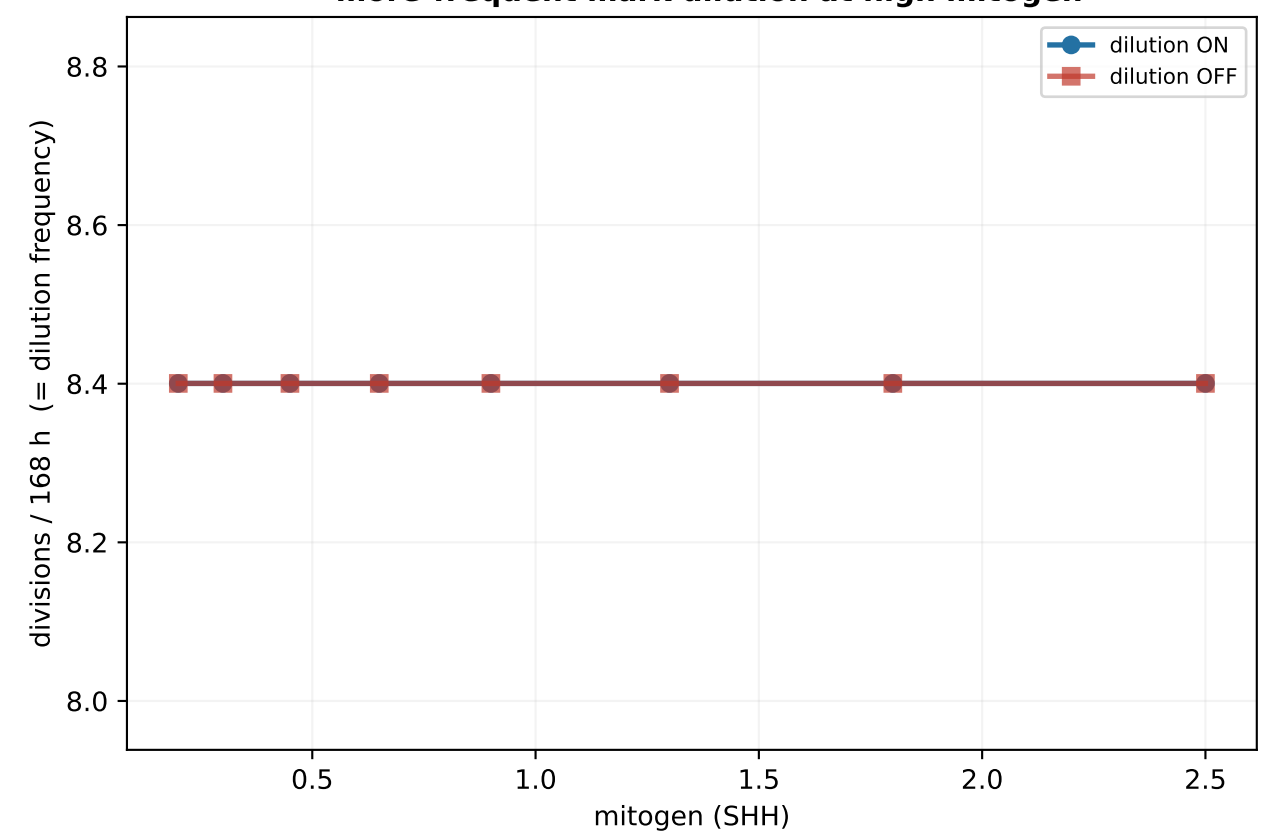


(B) Dilution holds the mark below its ceiling
— the gap widens as mitogen speeds the cycle



(C) Relieved repression → higher CyclinD1
(EZH2 reach limited by proliferation rate)





(D) The driver: replication rate rises with mitogen
→ more-frequent mark dilution at high mitogen
