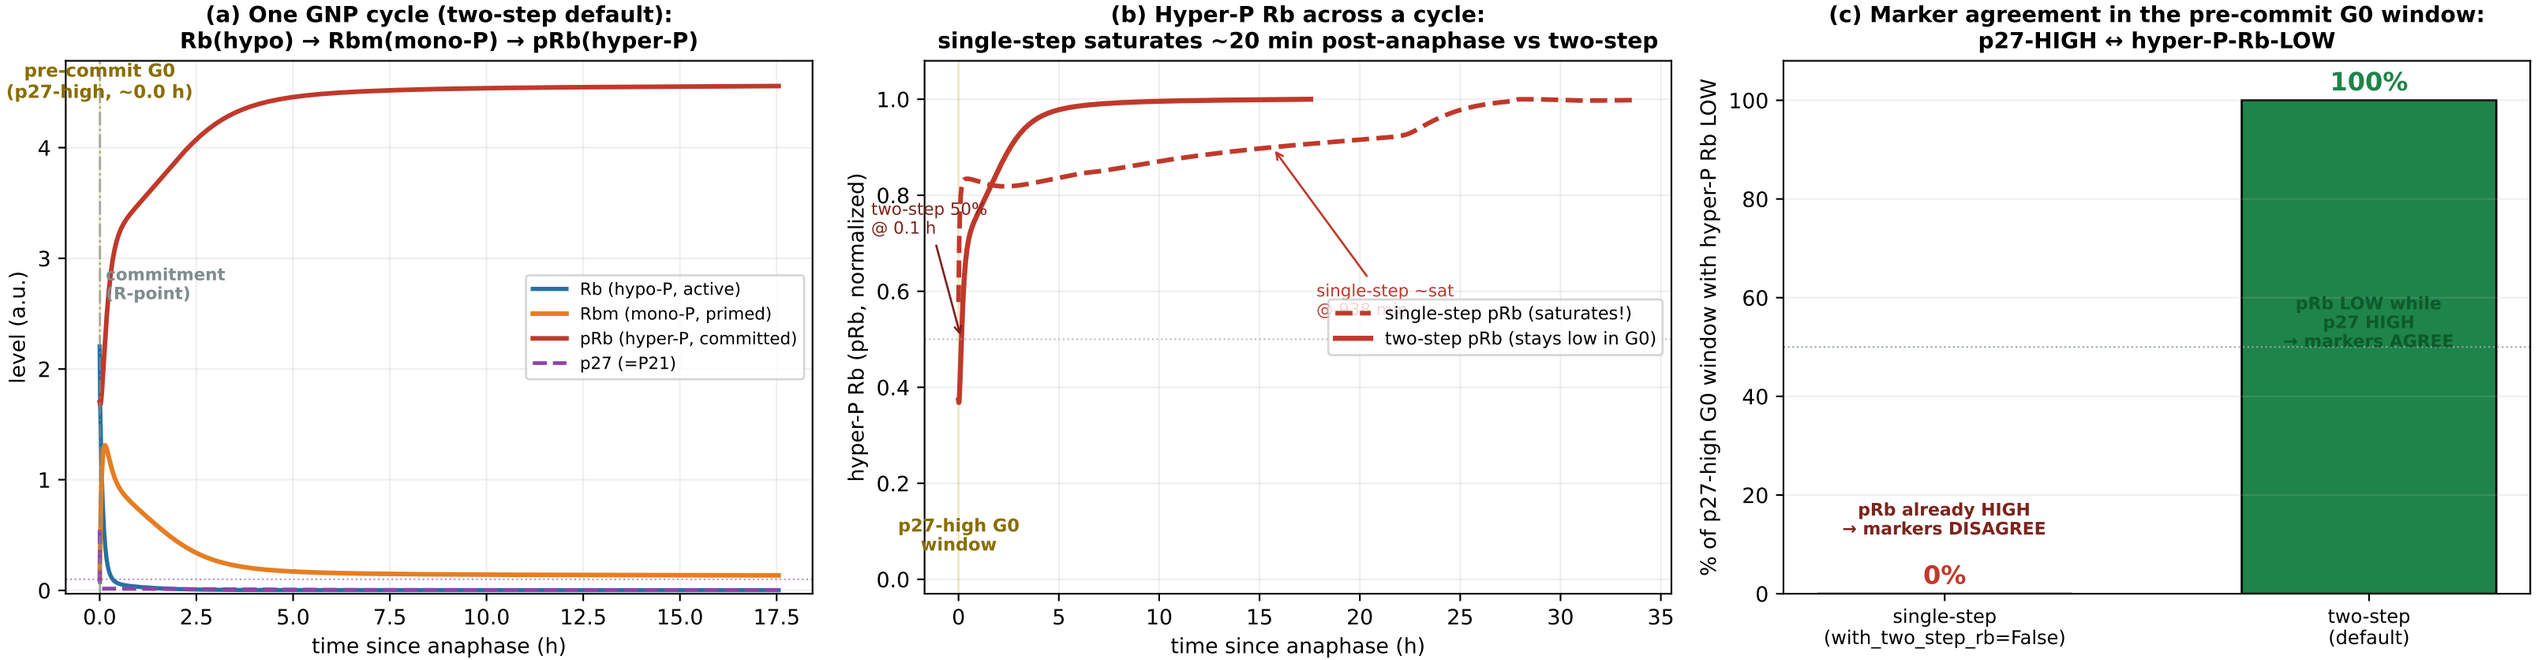
Two-step Rb switch restores hyper-P Rb as a faithful G0 / R-point marker (v44 default)


CyclinD-CDK4/6 primes Rb→Rbm (mono-P); CyclinE/A-CDK2 commits Rbm→pRb (hyper-P) at the R-point. GNP transient-G0 cell. Single-step pRb is high from anaphase (bad marker); two-step pRb stays low through G0 (good marker).
