

Hh withdrawal: H3K27me3 dilution race + transient-G0 WITH vs WITHOUT mark (calibrated + mu-distribution + partition noise, N=500/cond)

(A) Transient-G0 occupancy vs Hh — WITH vs WITHOUT mark

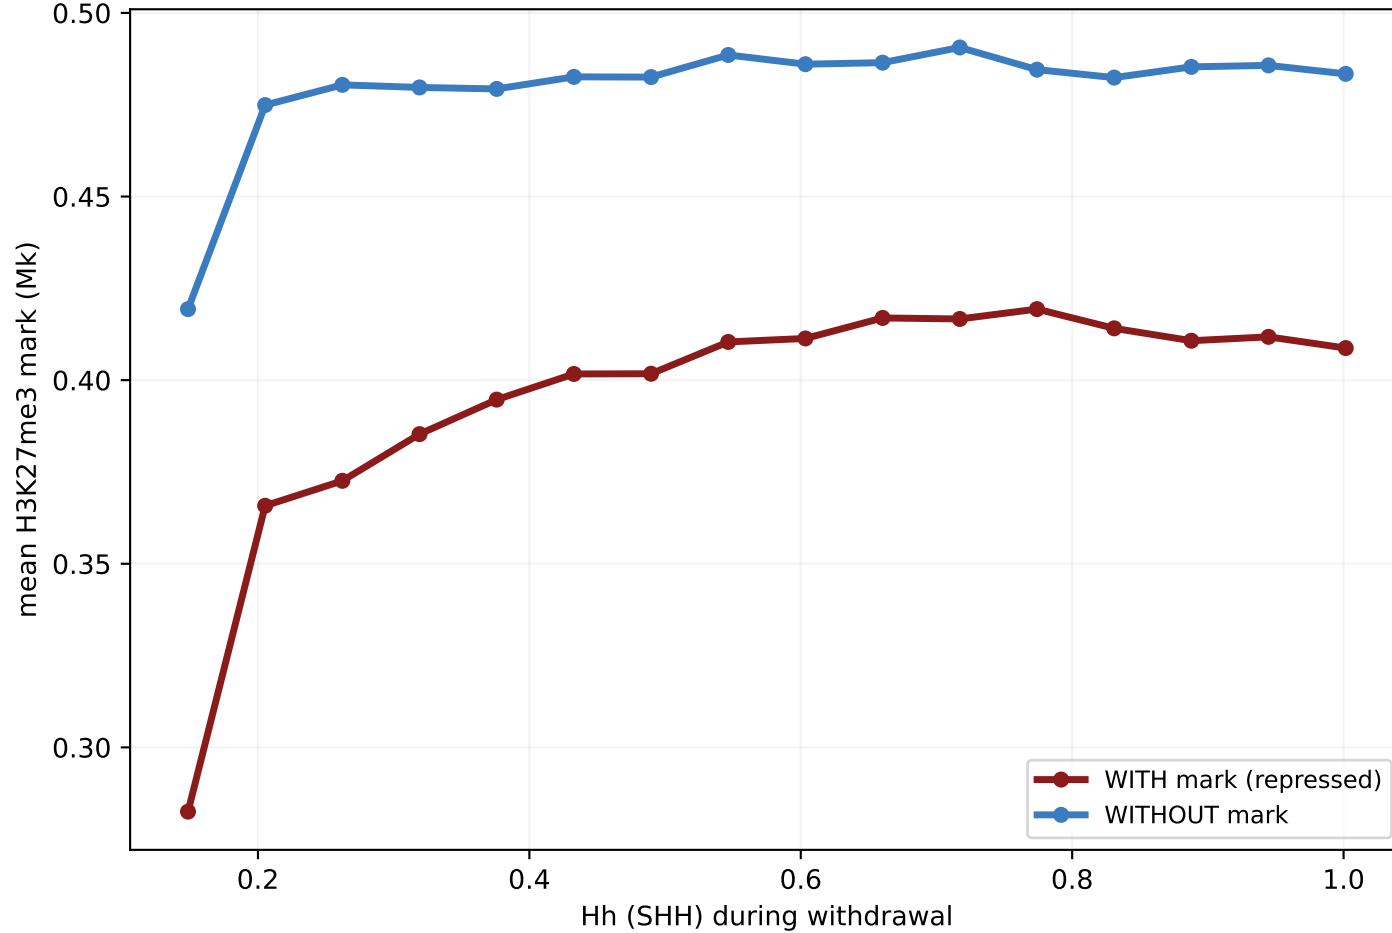

(B) Arrest occupancy vs Hh (context: where the transient-G0 goes)

(C) Mean mark FALLS as Hh withdraws — restoration is CYCLE-GATED

(EZH2 writer is E2f-gated → collapses as cells slow/arrest; WITH mark lower = more arrest → more EZH2 loss)

(D) The dilution-vs-restoration RACE (mu-distributed cells)

(fast → short period → diluted-LOW mark (regime 1); slow → PLATEAU (regime 2/3))
