

Response to an Hh DIP of varying DURATION — WITH vs WITHOUT H3K27me3 repression (baseline 0.8, dip 0.15, calibrated+mu+partition, N=500/cond)

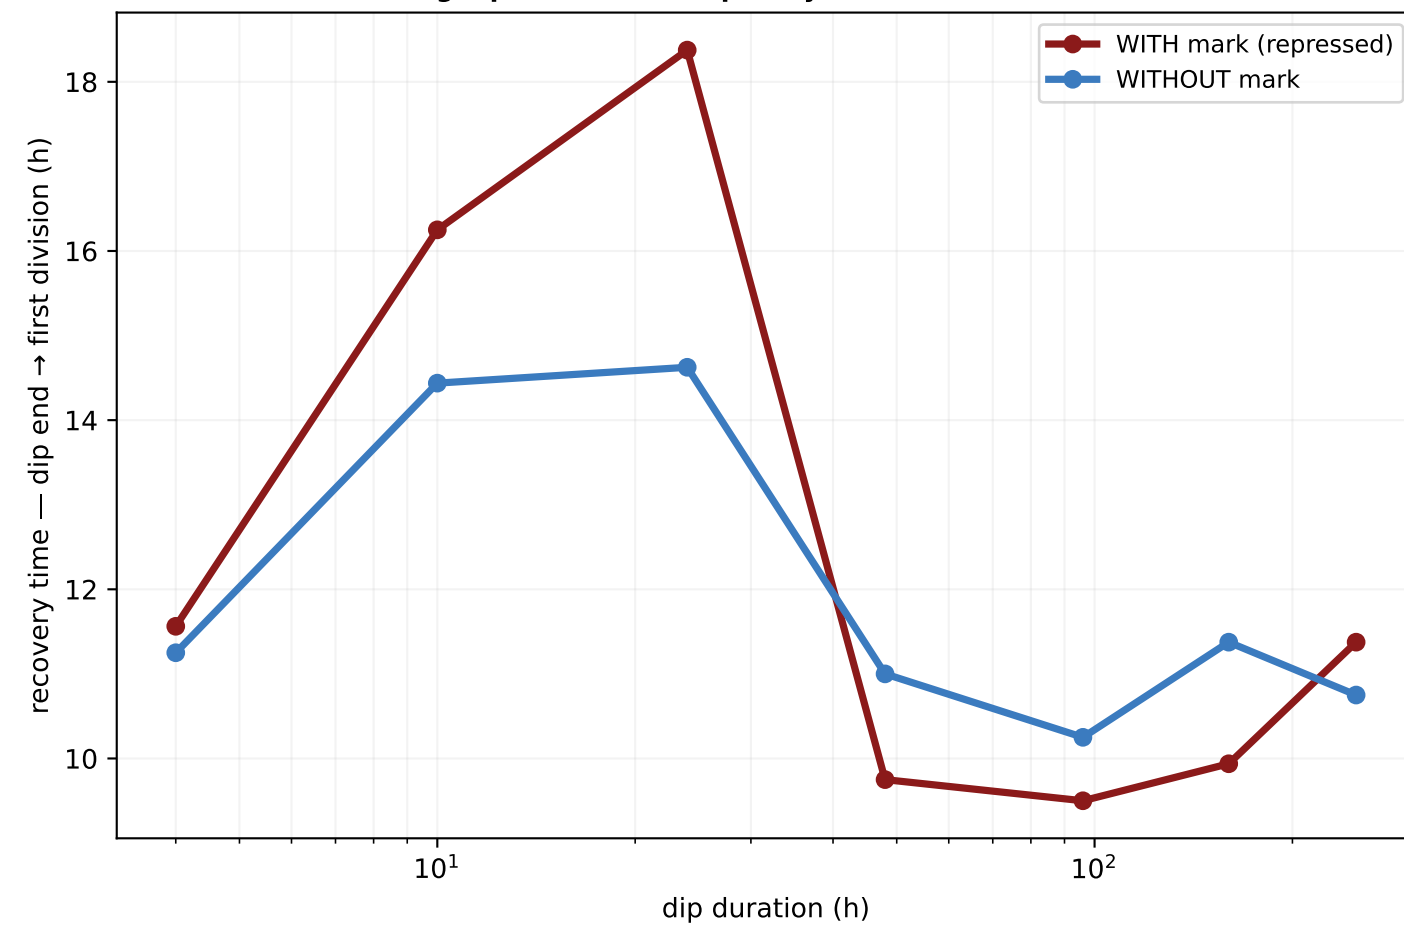

(A) Time-domain: a 48 h Hh dip — cycling (solid) & arrest (dotted)
WITH mark recovers slower / arrests more after the dip

(B) How long a dip causes IRREVERSIBLE exit?
WITH mark = arrest at SHORTER dips (lower threshold)

(C) Among cells that RECOVER: recovery is slower WITH the mark at short/mid dips (memory);
both fall at long dips = survivorship (only the fast/robust cells still recover)

(D) How deep/fast is the quiescence response to the dip itself?
